TALENT IN **TECH**NICOLOUR

JavaScript Project - PokéDom

# Overview

Using an array of pokémon and your knowledge of DOM manipulation in JavaScript, display information about 151 pokémon on your site. It should look like the reference image on this page.

[Starter Code Repository](#) (use the template to create your own repository)

# Notes

- You will not need to add any new files, and the only file you need to change is script.js. However feel free to play around with the index.html to find out how all the styles work.
- This should be hosted from your repository using GitHub Pages.
- If you haven't used imports in JavaScript before, take a look at the MDN Docs. You will need to find out how to import the pokemonArray from the pokemon.js file into the script.js file
- Look at the SCSS file for clues to what the HTML cards should look like
- We're looking for clean code here, make sure you remove extra console.logs and commented code, and remember to format your code!

## Extension

- Add the ability to filter through the pokémon, here are a couple of ideas:
  - Search by name
  - Be able to change the number of results
  - Filter by available types
